

Is the New Website Secure?

Why building the site with AI does not make it any less secure than any other professional WordPress site.

The core point: it does not matter who, or what, wrote the code.

A website's security comes from its code and its hosting, not from the tool used to build it. A human developer can write insecure code, and AI can write secure code. The safeguard is the architecture, the review, and the hosting. Not the author.

Myth versus reality

The worry	The reality
<i>"It was built with AI, so it must be easier to hack."</i>	Security depends on the code and the hosting, not on who or what wrote it. The code here is standard and fully auditable.
<i>"An AI-built site is a special, weaker kind of website."</i>	When live, it runs the exact same WordPress software that powers about 40 percent of the web. It is not a different or weaker version.
<i>"A human developer would make it safer."</i>	The author is not the safeguard. A developer can ship insecure code too. What protects a site is architecture, review, and hardened hosting.
<i>"We cannot verify what is inside it."</i>	Every file is human-readable, standard code. Any developer can open, review, and audit it at any time.

Two stages, both secure

NOW

A static prototype

No database, no login, no server-side code. Served over HTTPS on GitHub and Microsoft infrastructure. One of the lowest-risk website setups that exists.

AT LAUNCH

Standard WordPress on WP Engine

The same hardened, managed WordPress hosting used by countless professional businesses. Identical security model to any other WordPress site, built with the same standard theme code a developer would use.

What actually determines a WordPress site's security

These are the things that keep any WordPress site safe. They are applied the same way no matter who or what built the theme.

- ✓ Managed, hardened hosting on WP Engine: built-in firewall, malware scanning, automatic security patching, and daily backups.
- ✓ Two-factor authentication on every admin login, with strong, unique passwords.
- ✓ A small set of reputable plugins, kept up to date. Fewer plugins means fewer points of entry.
- ✓ A dedicated security plugin (Wordfence or Sucuri) and Cloudflare in front for an added firewall and bot protection.
- ✓ Enforced HTTPS across the site, plus a regular update and backup routine.

Already verified on the current build

- ✓ HTTPS is enforced on the live site. All connections are encrypted.
- ✓ No passwords, API keys, or secrets are exposed anywhere in the code.
- ✓ Customer and lead data is kept private and is never published with the site.
- ✓ Contact forms submit through a trusted third-party service over HTTPS, not through any server we have to secure ourselves.

The bottom line

The tool used to build a website has no effect on how secure it is. This site is built on standard, auditable code, and it will run on the same hardened WordPress hosting as any professionally built site. It can be reviewed by any developer at any time, and it is held to the same modern security standards as the rest of the web.
